# 1 Introduction to Emacs Lisp Byte Code and LAP

# 1.1 Why is Emacs Lisp Byte Code Important and How is Emacs as a Program Different?

If you were to look at two comparable complex programs circa 2018, Firefox 53.0.3 and Emacs 25.3, you would see that relative sizes of Firefox tarball is 5 times bigger than for Emacs. But how are these made up, or what languages are they comprised of?

For Firefox whose core is written in C++ we have:

```
$ cloc --match-f='\.(js|c|cpp|html|py|css)$' firefox-53.0.3
89156 text files.
86240 unique files.
1512 files ignored.
```

cloc v 1.60 T=244.20 s (353.2 files/s, 56012.8 lines/s)

Language	files	comment	code
C++	7267	418019	3057110
Javascript	25855	532629	2859451
HTML	45311	120520	2209067
С	3482	400594	1664666

And for Emacs whose core is written in C we have:

```
$ cloc emacs-25.3.tar.xz
    3346 text files.
    3251 unique files.
    1130 files ignored.
```

cloc 1.60 T=13.85 s (160.1 files/s, 154670.7 lines/s)

Language	files	comment	code
Lisp	1616	200820	1270511
C	255	66169	256314
C/C++ Header	176	11505	34891

If you look at the relative ratio of C++ versus Javascript code in Firefox, and the ratio of C versus Lisp code in Emacs, you'll see that there is much more of Emacs written in Lisp than say of Firefox written in Javascript. (And if you look at the C code for Emacs, a lot of it looks like Lisp written using C syntax). My take is that Emacs a lot more orthogonal in its basic concepts and construction. Just as Leibniz was amazed that such diversity could come out of such simple rules of mathematics and physics, so it is remarkable that something as complex as Emacs can come out of the relatively simple language Lisp.

## 1.2 Emacs Lisp Byte Code and LAP

However pervasively used, Emacs Lisp is in making up the Emacs ecosystem, Emacs Lisp is not and never has been a speedy language compared to say, C, C++, Go, Rust, or Java. And that's where LAP and bytecode come in.

As stated in a commment in byte-opt.el added circa 1996:

No matter how hard you try, you can't make a racehorse out of a pig.

You can, however, make a faster pig.

—Eric Naggum

Emacs Lisp bytecode is the custom lower-level language used by Emacs' bytecode interpreter. As with all bytecode, bytecode instructions are compact. For display purposes, there is a disassemble command that unpacks the fields of the instruction. With this and the constants vector, bytecode can be printed in an assembly-language-like format.

I'll often use Emacs Lisp bytecode instruction refer to an assembly representation of an Emacs Lisp bytecode instruction.

LAP stands for Lisp Assembly Program. It is an internal representation of the bytecode instructions in a more symbolic form. It is used behind the scenes to that make bytecode more amenable to optimization, since the instructions are in a structure which is easier to operate on.

If you want to write the instruction sequence in this symbolic form rather than give a byte-encoded form, you can do that using the function byte-compile-lapcode.

## Example showing use of byte-compile-lapcode

Silly Loop Example (https://www.gnu.org/software/emacs/manual/html\_node/elisp/Speed-of-Byte\_002dCode.html) in the Emacs Lisp Manual gives a program to time running in some code Bytecode interpreter versus running the code in the Lisp interpreter. When I ran this program, bytecode ran 2.5 times faster<sup>1</sup>. The Emacs Lisp manual gets a speed improvement of about 3 times.

<sup>&</sup>lt;sup>1</sup> Code was compiled to use dynamic binding for variable access, same as was probably used in the Emacs Lisp manual. We should note that, byte-compiling with lexical binding for variable access gives code that runs a bit faster than when dynamic binding is used.

## 1.3 Emacs Lisp Virtual Machine

The Emacs Lisp bytecode interpreter, like many bytecode interpreters such as Smalltalk, C Python, Forth, or PostScript, has an evaluation stack and a code stack. Emacs Lisp Bytecode instructions come in the order used in Reverse Polish Notation: operands appear prior to the operator. This is how many other bytecode interpreters work. It is the opposite of the way Lisp works. Thus, to add the values of two variables we might write (+ a b). However in bytecode it is the other way around: the operator or function comes last. So the corresponding bytecode is:

```
0 varref a
1 varref b
2 plus
```

As in most language-specific virtual machines, but in contrast to a typical a number of general-purpose virtual machines, the things that are on the evaluation stack are the same objects as found in the system that they model. Here, these objects can include Emacs buffers, or font faces, Lisp objects like hashes or vectors, or simply (30-bit) Lisp integers. Compare this with say LLVM IR, or JVM instructions where the underlying objects on the stack are registers which can act as pointers and the internal memory layout of objects is exposed.

Control flow in Lisp bytecode is similar to a conventional assembly language: there are unconditional and conditional jumps. More complex control structures are simply built out of this.

Although it may be obvious, one last thing I'd like to point out is that the Emacs Lisp bytecode instruction set is custom to Emacs. In addition to primitives that you'd expect for Lisp like "car" and "cdr", there are primitive bytecodes for more complex Emacs editor-specific concepts like "save-excursion".

The interpreter is largely backwards compatible, but not forwards compatible<sup>2</sup>. So old versions of Emacs can't run new byte code. Each instruction is between 1 and 3 bytes. The first byte is the opcode and the second and third bytes are either a single operand, a single immediate value. Some operands are packed into the opcode byte.

<sup>&</sup>lt;sup>1</sup> The fact that the semantic level difference between Emacs Lisp and its bytecode is not great makes writing a decompiler for it more feasible than if the bytecode language were of a general nature such as say LLVM IR.

 $<sup>^{2}\,</sup>$  well, eventually old Emacs Lisp by tecode instructions do die

## 2 Emacs Lisp Byte-Code Environment

In this chapter we will discuss the ways Emacs creates, modifies and uses bytecode in order to run code. We describe a little of the two kinds of interpreters Emacs has, what goes into a bytecode file, and the interoperability of bytecode between versions.

## 2.1 Byte-Code Objects

Emacs Lisp bytecode isn't a low-level sequence of octets (bytes) that requires a lot of additional special-purpose machinery to run. There is however custom C code interpreter to handle each of the instruction primitives, and that is basically it. And even here, many of the instructions are simply a bytecode form of some existing Emacs primitive function like "car" or "point".

Emacs Lisp bytecode is a built-in Emacs Lisp type (same as a say a Lisp "cons" node, or a Lisp symbol). You can check if a value is bytecode using the byte-compile-function-p predicate function. Functions aref and mapcar can be used extract the components of bytecode once it is built, the bytecode object is made up of other normal Emacs Lisp objects described next. Byte code is created using the make-byte-code function.

One important component of the bytecode object is the "constants vector." It contains important Lisp Objects that are required to make sense of the bytecode-instruction operands: functions that share the same bytecode-instruction byte string, but differ in their constants vectors, can do very different things.

#### 2.1.1 The Byte-Code Function Type and Literal

This section is largely lifted from Chris Wellons' Emacs byte code Internals. See references at the end of this doc.

An Emacs Lisp object of a byte code type is analogous to an Emacs Lisp vector. As with a vector, elements are accessed in constant time.

The print syntax of this type is similar to vector syntax, except #[...] is displayed to display a bytecode literal instead of ([...] as is used in a vector.

In contrast to vector object, there are no functions to index or extract parts of a code object once it is build, and a byte-code object can be evaluated as a function. Valid byte-code objects have 4 to 6 elements and each element has a particular structure elaborated on below.

There are two ways to create a byte-code object: using a byte-code object literal or with make-byte-code. Like vector literals, byte-code functions don't need to be quoted.

Examples of calling make-byte-code:

```
(make-byte-code 0 "" [] 0)
;; => #[0 "" [] 0]

#[1 2 3 4]
;; => #[1 2 3 4]

(#[0 "" [] 0])
;; error: Invalid byte opcode
```

The elements of a bytecode function literal are:

- 1. Function parameter (lambda) list
- 2. Byte-code Unibyte String
- 3. Constants Vector
- 4. Maximum Stack Usage

- 5. Docstring
- 6. Interactive Specification

#### 2.1.1.1 Function Parameter List

The first element of a bytecode-function literal is the parameter list for the lambda. The object takes on two different forms depending on whether the function is lexically or dynamically scoped. If the function is dynamically scoped, the argument list is exactly what appears in Lisp code.

#### Example showing how a parameter list is transformed:

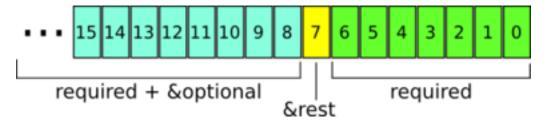

```
(setq lexical-binding nil) ; force lexical binding
(byte-compile
  (lambda (a b &optional c) 5))
;; => #[(a b &optional c) "\300\207" [5] 1]
```

Above we show raw bytecode data. in Emacs after versions after 25 efforts have been made to hide the data.

There's really no shorter way to represent the parameter list because preserving the argument names is critical. Remember that, in dynamic scope, while the function body is being evaluated these variables are globally bound (eww!) to the function's arguments.

On the other hand, when the function is lexically scoped, the parameter list is packed into an Emacs Lisp integer, indicating the counts of the different kinds of parameters: required, &optional, and &rest. No variable names are needed.

The following shows how parameter counts and flags are encoded:

The least significant 7 bits indicate the number of required arguments. Notice that this limits compiled, lexically-scoped functions to 127 required arguments. The 8th bit is the number of &rest arguments (up to 1). The remaining bits indicate the total number of optional and required arguments (not counting &rest). It's really easy to parse these in your head when viewed as hexadecimal because each portion almost always fits inside its own "digit."

#### Example showing how lexical parameters are encoded:

```
(byte-compile-make-args-desc '())
;; => #x000 (0 args, 0 rest, 0 required)
(byte-compile-make-args-desc '(a b))
;; => #x202 (2 args, 0 rest, 2 required)
(byte-compile-make-args-desc '(a b &optional c))
;; => #x302 (3 args, 0 rest, 2 required)
```

```
(byte-compile-make-args-desc '(a b &optional c &rest d))
;; => #x382 (3 args, 1 rest, 2 required)
```

The names of the arguments don't matter in lexical scope: they're purely positional. This tighter argument specification is one of the reasons lexical scope is sometimes faster: the byte-code interpreter doesn't need to parse the entire lambda list and assign all of the variables on each function invocation; furthermore, variable access is via a compact index located usually in the operand value rather than an index into the constants vector followed by a lookup of the variable.

### 2.1.1.2 Byte-code Unibyte String

The second element of a bytecode-function literal is a unibyte string — it strictly holds octets and is not to be interpreted as any sort of Unicode encoding. These strings should be created with unibyte-string because string may return a multibyte string. To disambiguate the string type to the lisp reader when higher values are present (> 127), the strings are printed in an escaped octal notation, keeping the string literal inside the ASCII character set.

#### Example of a unibyte string:

```
(unibyte-string 100 200 250);; => "d\310\372"
```

It's unusual to see a byte-code string that doesn't end with 135 (#o207, return). Perhaps this should have been implicit? I'll talk more about the byte code below.

#### 2.1.1.3 Constants Vector

The third object in a bytecode-function literal is a constants vector. It's a normal Emacs Lisp vector and can be created with (vector ...) or a vector literal.

In addition to the normal kinds of things one thinks of as constants — numbers, strings, and compositions of these — the constants vector importantly contains symbol constants of those dynamic variables and function names which are referred to by the instructions of the byte-code unibyte string.

The amount of space used by an Emacs byte-code instruction, and the number of ways an operand in an instruction can refer to an Lisp object is rather limited. Most operands are only a few bits in length, some fill an entire byte, and occasionally an operand can be two bytes in length. Given this, you can't have an arbitrary string or structured Lisp object listed directly inside an operand. Instead, operands reference either the constants vector or they index into the evaluation stack itself.

#### Example showing a constants vector:

The above assumes that dynamic binding is in effect.

The constants vector in the above example contains 5 elements:

- a the symbol a which refers to a variable
- myfunc the symbol myfunc which likely refers to an external function
- ("hi" "there") a list constant containing two strings
- nil the nil constant
- 5 the integer constant 5

The properties of symbol a and symbol myfunc are consulted at run time, so as such there is no knowledge in the bytecode representing the fact that a is a dynamically-bound parmeter while my-func is probably an external function.

If the lambda were a lexically-scoped, the constants vector would not have the variable symbol a listed, but instead there would be a stack entry.

Note that although the symbol **b** is a parameter of the lambda, it doesn't appear in the constants vector, since it is not used in the body of the function.

### 2.1.1.4 Maximum Stack Usage

The fourth object in a bytecode-function literal is an integer which gives the maximum stack space used by this byte-code. This value can be derived from the byte code itself, but it's pre-computed so that the byte-code interpreter can quickly check for stack overflow. Under-reporting this value is probably another way to crash Emacs.

In our example above, maximum-stack value is five since function myfunc is called with four parameters which are pushed onto the stack, and there is an additional stack entry pushed the myfunc symbol itself. All of this needs to be in place on the stack just before a call instruction runs to perform the myfunc call.

#### 2.1.1.5 Docstring

The fifth object in a bytecode-function literal is simple and completely optional. Depending on how the function was created the docstring is either the docstring, or a cons cell indicating a compiled '.elc' and a position for lazy access. Only one position, the start, is needed because the lisp reader is used to load it and it knows how to recognize the end.

## 2.1.1.6 "Interactive" Specification

When there is a sixth field in the bytecode-function the function is a command, i.e an "interative" function. Otherwise the function is not a command. That parameter holds the exactly contents of the argument to interactive in the uncompiled function definition. Note that (interactive) causes the sixth field to be nil, which is distinct from there not being a sixth feild.

#### Examples showing the interactive specification:

The interactive expression usually interpreted, which is fine because, by definition, this code is going to be waiting on user input. However, it slows down keyboard macro playback.

## 2.2 Byte-Code Compiler

The Byte-Code compiler is an ahead-of-time compiler that accepts Emacs Lisp input and produces bytecode that can be run by Emacs. The compiler itself is written in Emacs Lisp<sup>1</sup>, and is a comparatively compact program contained in the files bytecomp.el and byte-opt.el.

Internally, the compiler first produces an intermediate Lisp structure in LAP code, then performs various optimizations on that, and finally translates the LAP code into bytecode. LAP code is used during compilation, but not kept in memory or used when running bytecode.

It is possible to go back to LAP code from bytecode; this is done in order to inline functions and when bytecode disassembly is requested.

 $<sup>^{1}</sup>$  usually, the compiler itself is compiled into bytecode, which avoids overflow problems

## 2.3 Byte-Code Interpreter

When a function is called and the function is represented as bytecode, control passes to the bytecode interpreter. The interpreter is written in C and is written more for speed than readability.

The bytecode interpreter operates on a single function at a time; for a function call, the bytecode interpreter calls other parts of Emacs, which might call the bytecode interpreter again, recursively. Thus, in contrast to languages like FORTH, there is no code stack per se, just the C stack.

The bytecode interpreter implements a stack machine utilizing a fixed-size evaluation stack, which is usually allocated as a block on the C stack. Instructions can access either this stack or a constants vector, which is produced at compile time and made part of the bytecode object.

The evaluation stack, as well as the constants vector, contains Lisp values, usually 64-bit words containing an integer (Emacs integers are limited to 62 bits on 64-bit machines), symbol index, or a tagged pointer to one of various Emacs structures such as markers, buffers, floating-point numbers, vectors, or cons cells.

Values on the evaluation stack are created at run time; values in the constants vector are created when the byte-compiled file is read and converted into bytecode objects. The underlying bit representation of values in the constants vector can vary between Emacs instances: they are constants in the sense that they do not vary within a single Emacs instance.

Bytecode objects contain a number safely estimating the maximum stack size the evaluation stack can grow to.

## 2.4 Byte-Code Instructions

The bytecode interpreter, once it has set up the evaluation stack and constants vector, executes the instructions that make up the bytecode byte string: each instruction is between one and three bytes in length, containing an opcode in the first byte and sometimes an eightor 16-bit integer in the following bytes. Those integers are usually unsigned, and 16-bit integers are stored in little-endian byte order, regardless of whether that is the natural byte order for the machine Emacs runs on.

Some opcodes, allocated in blocks, encode an integer as part of the opcode byte.

Bytecode instructions operate on the evaluation stack: for example, plus, the addition function, removes two values from the top of the stack and pushes a single value, the sum of the first two values, back on the stack.

Since the arguments for a function call need to be on the stack before the function can operate on them, bytecode instructions use Reverse Polish Notation: first the arguments are pushed on the stack, then the function or operation is called. For example, the Lisp expression (+ a b) turns into this bytecode:

```
PC Byte Instruction
0 8 varref a
1 9 varref b
2 92 plus
```

First a and b are dereferenced and their values pushed onto the evaluation stack; then plus is executed, leaving only a single value, the sum of a and b, on the stack.

## 2.5 Byte-Code Files

When Emacs is build from source code, there is C code for some primitive or built-in functions. These include Lisp functions like car, or primitive Emacs functions like point. Other equally important functions are implemented in Emacs Lisp. These are byte compiled and then loaded into Emacs. On many systems there is the ability to dump Emacs in some kind of image format after these basic functions have been loaded. But even if that doesn't happen, a file called loaddefs.el is created that contains many of the important basic primitive functions as bytecode.

When you invoke Emacs then, it has a number of functions already loaded and these are either coded in C or have been byte compiled and loaded. Before running a function, Emacs queries the type of code that is associated with the function symbol and calls either its lambda S-expression interpreter or its bytecode interpreter.

When you run load, which reads and evaluates Lisp code from a file, at the top-level it doesn't matter whether the file contains bytecode or Emacs Lisp source code. Either way the only thing done is to open the file, and read the contents of the file using the normal Lisp reader. The difference between the two kinds of files is more about convention than it is strictly about the contents of the file.

The difference between a Emacs Lisp bytecode file and a Emacs Lisp source file, then is two things. First the bytecode file will have a comment header in it that starts ;ELC^W^@^@^@ while the source code probably doesn't. (However there's nothing to stop you from adding in that line if you feel like it). In addition to this comment header, a bytecode file will have other meta-comments such as which version of Emacs was used to compile the file and whether optimization was used. In earlier versions, there was information about the program that was used to compile the program was given, like its version number. And the source code path used to be in there as well. (I think these things should still be in there but that's a different story). See Chapter 4 [Instruction Changes Between Emacs Releases], page 137, where we give examples of the headers to show how that has changed.

The second thing that is typically different between source code files and bytecode files is the prevalence of the byte-code calls used in the file and with the inclusion of those comes a lack of any defun, defmacro, or lambda calls. But again I suppose there's nothing stopping you from using doing likewise in your source code.

In fact, you can take a file with the .elc extension, rename it to have an .el extension instead and load that. And that will run exactly the same if it had been loaded as a byte code file<sup>1</sup>.

Similarly, just as you can concatenate any number of independent Emacs Lisp source code files into one file<sup>2</sup>, you can do the same with Emacs Lisp bytecode files.

Of course, there will probably certain programs that are fooled when the extension is changed. In particular, the byte-recompile-directory function it will think that the bytecode file doesn't exist because it has the wrong extension. So even though Emacs is permissive about such matters, it is best to stick with the normal Emacs conventions.

If you go the other direction and rename a Lisp file as a bytecode file, Emacs will notice the discrepency because at the top of the file is a header that Emacs checks. But if you add a reasonable-looking header you can go that direction as well.

 $<sup>^{2}\,</sup>$  and this is sometimes done as a poor-man's way to create a package

The final thing that should be mentioned when talking about bytecode files is interoperability between Emacs versions.

Even though a bytecode header has a meta comment indicating the version of Emacs that was used to compile it, that information is not used in determining whether the bytecode file can be run or not.

This has the benefit of being able to run bytecode compiled in different Emacs version than the version you are currently running. Since Emacs bytecode instructions do not change that often, this largely works. The scary part though is that opcode meanings have changed over the 30 years, and the interpreter is and has been sometimes lacking in checks. (In the past the interpreter has aborted when running an invalid bytecode). So Emacs doesn't even know that you are running bytecode from a different interpreter. There is no check that you aren't going off a cliff running older or newer bytecode.

However, Emacs developer(s) maintain that in practice problems haven't occurred with such frequency that it has been reported happened enough to be a problem. Also, they try to keep backward compatability between versions. In other words, bytecode that was generated in an older version of Emacs but is no longer generated will often still be interpreted in the new version of Emacs. While this is a nice intention, the facts seem to suggest that this isn't always the case. (Nor could it be in reality for a program that is 30 years old or so).

See Chapter 4 [Instruction Changes Between Emacs Releases], page 137, then for when this is likely to work and in what cases it won't. And although running newer bytecode in an older version of Emacs isn't explicitly considered, again, since bytecode doesn't change that often, in reality this too can sometimes work out.

Note that this is in sharp contrast other bytecode interpreters like Python where the magic used in compiling has to be the same as the value of running interpreter or Python will refuse to run.

Personally, I think it would be nice to have a Emacs Lisp bytecode checker, perhaps a safer-load function that does look at the bytecode and its meta-comments gleans when there is something that is known to cause problems. Any voluneers?

## 3 Emacs Lisp Byte-Code Instructions

## 3.1 Instruction-Description Format

In this chapter we'll document instructions over the course of the entire history of Emacs. Or at least we aim to.

For the opcode names, we will prefer canonicalized names from the Emacs C source bytecode.c (under directory src/) when those differ from the names in bytecomp.el (under directory lisp/emacs-lisp). Most of the time they are the same under the transformation described below.

We use names from bytecode.c because that is a larger set of instruction names. Specifically, obsolete instructions names (both those that can be interpreted even though they are no longer generated, and some that are no longer interpreted) are defined in that file, whereas that is not the case in bytecomp.el.

Names in bytecode.c must follow C conventions and must be adjusted to harmonize with other C names used. But this aspect isn't of use here, so we canonicalize those aspects away.

For example, in bytecode.c there is an opcode whose name is Bbuffer\_substring. We will drop the initial B and replace all underscores (\_) with dashes (-). Therefore we use buffer-substring.

The corresponding name for that opcode in bytecomp.el is byte-buffer-substring. For the most part, if you drop the initial byte- prefix in the bytecomp.el name you will often get the canonic name from bytecode.c.

However this isn't always true. The instruction that the Emacs Lisp save-current-buffer function generates nowadays has opcode value 114. In the C code, this value is listed as B\_save\_current\_buffer\_1; bytecomp.el uses the name byte-save-current-buffer. We report the instruction name for opcode 114 as save-current-buffer-1.

To shorten and regularize instruction descriptions, each instruction is described a standard format. We will also require a small amount of jargon. This jargon are explained below.

### 3.1.1 Instruction Jargon

- TOS The value of top of the evaluation stack. Many instructions either read or push onto this.
- S This is an array of evaluation stack items. S[0] is the top of the stack, or TOS.
- top A pointer to the top of the evaluation stack. In C this would be &TOS. When we want the stack to increase in size, we add to top. For example, to makes space to store a new single new value, we can use top++ and then assign to TOS.
  - Note that in changing top, the value accessed by TOS or S values all change.
- $\phi$  This is used in describing stack effects for branching instructions where the stack effect is different on one branch versus the other. This is a function of two arguments. The first argument gives the stack effect on the non-nil branch and the second argument gives the stack effect for the nil branch. So  $\phi(0,-1)$  which is seen in goto-if-not-nil-else-pop means that if the jump is taken, the stack effect is 0, otherwise the effect removes or pops an evaluation-stack entry.

• instruction-name subscripting ([]) In many instructions such as constant, varref, you will find an index after the instruction name. What's going on is that instruction name is one of a number of opcodes in a class encodes an index into the instruction. We generally call this an "Argument-encoding" instruction. In the display of the opcode in assembly listings and in the opcode table chapter where we list each opcode, we will include that particular instruction variant in subscripts.

For example consider constant [0] versus constant [1]. The former has opcode 192 while the latter has opcode 193. In terms of semantics, the former is the first or zeroth-index entry in a function's constant vector while the latter is the second or 1-index entry.

### 3.1.2 Instruction Description Fields

The description of fields use for describing each instruction is as follows

#### **Implements:**

A description of what the instruction does.

#### Generated via:

These give some Emacs Lisp constructs that may generate the instruction. Of course there may be many constructs and there may be limiting situations within that construct. We'll only give one or a few of the constructs, and we'll try to indicate a limiting condition where possible.

**Operand:** When an instruction has an operand, this descripts the type of the operand. Note that the size of the operand (or in some cases the operand value) will determine the instruction size.

#### Instruction size:

The number of bytes in the instruction. This is 1 to 3 bytes.

#### Stack effect:

This describes how many stack entries are read and popped and how many entries stack entries are pushed. Although this is logically a tuple, we'll list this a tuple like (-3,2) as a single scalar -3+2. In this example, we read/remove three stack entries and add two. The reason we give this as -3+2 rather than the tuple format is so that the overall effect (removing a stack entry) can be seen by evaluating the expression.

**Added in:** This is optional. When it is given this gives which version of Emacs the opcode was added. It may also give when the opcode became obsolete or was no longer implemented.

**Example:** Some Emacs Lisp code to show how the instruction is used. For example the for the goto instruction we give:

```
(defun goto-eg(n)
  (while (n) 1300))
generates:
PC Byte Instruction
  0 192 constant[0] n
  1 32 call[0]
```

#### Constants Vector: [n]

From the above we see that the goto instruction at program counter (PC) 5, has decimal opcode 130. The instruction is three bytes long: a one-byte opcode followed by a two-byte operand.

The instruction name at PC 0 with opcode 192, constant[0], looks like it is indexing, but it is a just name, where the brackets and number are part of the name. We use this kind of name because it is suggestive of how it works: it indexes the first element into the constants vector and pushes that value onto the evaluation stack. constant[1] with opcode 193 pushes the second element of the constants vector onto the stack. We could have also used instruction names like constant0 and constant1 for opcodes 192 and 193 instead.

Unless otherwise stated, all code examples were compiled in Emacs 25 with optimization turned off.

## 3.2 Argument-Packing Instructions

These instructions from opcode 1 to 47 encode an operand value from 0 to 7 encoded into the first byte. If the encoded value is 6, the actual operand value is the byte following the opcode. If the encoded value is 7, the actual operand value is the two-byte number following the opcode, in Little-Endian byte order.

```
stack-ref (1-7)
```

Reference a value from the evaluation stack.

#### **Implements:**

top++; TOS <- S[i+1] where i is the value of the instruction operand.

#### Generated via:

let, let\* and lambda arguments.

**Operand:** A stack index

#### Instruction size:

1 byte for stack-ref[0] .. stack-ref[4]; 2 bytes for stack-ref[5], 8-bit operand; 3 bytes for stack-ref[6], 16-bit operand.

Stack effect:

```
-0 + 1.
```

Added in: Emacs 24.1. See Section 4.7 [Emacs 24], page 142.

**Example:** When lexical binding and optimization are in effect,

generates:

```
Byte
PC
          Instruction
    192
          constant[0] 5 ;; top++; TOS <- 5</pre>
 1
    193
          constant[1] 6 ;; top++; TOS <- 6</pre>
 2
    194
          constant[2] 7 ;; top++; TOS <- 7
 3
      2
          stack-ref[2] ;; top++; TOS <- S[3] (5)
 4
      1
          stack-ref[1] ;; top++; TOS <- S[2] (7)
 5
     92
          plus
 6
    135
          return
```

Constants Vector: [5 6 7]

Warning Running an instruction with opcode 0 (logically this would be called stack-ref[0]), will cause an immediate abort of Emacs in versions after version 20 and before version 25! The abort of the opcode was in place before this instruction was added.

Zero is typically an invalid in bytecode and in machine code, since zero values are commonly found data, e.g. the end of C strings, or data that has been initialized to value but represents data that hasn't been written to yet. By having it be an invalid instruction, it is more likely to catch situations where random sections of memory are run such as by setting the PC incorrectly.

## varref (8–15)

## varref (8-15)

Pushes the value of the symbol in the constants vector onto the evaluation stack.

#### **Implements:**

top++; TOS <- (eval constants\_vector[i]) where i is the value of instruction operand

#### Generated via:

dynamic variable access

**Operand:** A constants vector index. The constants vector item should be a variable symbol.

#### Instruction size:

1 byte for varref[0] .. varref[4]; 2 bytes for varref[5], 8-bit operand; 3 bytes for varref[6], 16-bit operand.

#### Stack effect:

-0 + 1.

**Example:** When dynamic binding is in effect,

(defun varref-eg(n)
n)

generates:

PC Byte Instruction
0 8 varref[0] n
1 135 return

Constants Vector: [n]

## varset (16-23)

## varset (16-23)

Sets a variable listed in the constants vector to the TOS value of the stack.

#### **Implements:**

constants\_vector[i] <- TOS; top-- where i is the value of the instruction
operand.</pre>

**Operand:** A constants vector index. The constants vector item should be a variable symbol.

#### Instruction size:

1 byte for varset[0] .. varset[4]; 2 bytes for varset[5], 8-bit operand; 3 bytes for varset[6], 16-bit operand.

#### Stack effect:

-0 + 1.

**Example:** When dynamic binding is in effect,

```
defun varset-eg(n)
  (setq n 5))
```

#### generates:

```
PC Byte Instruction
0 193 constant[1] 5
1 137 dup
2 16 varset[0] n;; sets variable n
3 135 return
```

Constants Vector: [n 5]

## varbind (24–31)

## varbind (24-31)

Binds a variable to a symbol in the constants vector, and adds the symbol to a special-bindings stack.

#### Implements:

(set\_internal(constants\_vector[i]) where i is the value of the instruction operand.

#### **Instruction size:**

```
1 byte for varbind[0] .. varbind[4]; 2 bytes for varbind[5], 8-bit operand; 3 bytes for varbind[6], 16-bit operand.
```

#### Stack effect:

```
-0 + 1.
```

**Example:** When dynamic binding is in effect,

#### generates:

```
Byte Instruction
  193
         constant[1] 1
1
  137
   24
        varbind[0] c ;; creates variable c
3
   84
4
        unbind[1]
                      ;; removes variable c
   41
5
  135
        return
```

Constants Vector: [c 1]

## call (32-39)

## call (32-39)

Calls a function. The instruction argument specifies the number of arguments to pass to the function from the stack, excluding the function itself.

#### **Implements:**

(set\_internal(constants\_vector[i]) where i is the value of the instruction operand.

#### Instruction size:

1 byte for call[0] .. call[4]; 2 bytes for call[5], 8-bit operand; 3 bytes for call[6], 16-bit operand.

#### Stack effect:

```
-0 + 1.
```

(defun call-eg()

#### Example:

```
(exchange-point-and-mark)
  (next-line 2))
generates:
PC Byte Instruction
   192
         constant[0] exchange-point-and-mark
    32
         call[0]
   136
        discard
 3 193
        constant[1] next-line
 4
   194
         constant[2] 2
 5
    33
         call[1]
 6
   135
         return
```

Constants Vector: [exchange-point-and-mark next-line 2]

## unbind (40-47)

## unbind (40-47)

Remove the binding of a variable to symbol and from the special stack. This is done when the variable is no longer needed.

#### **Implements:**

undo's a let, unwind-protects, and save-excursions

#### Generated via:

let in dynamic binding. Balancing the end of save-excursion.

#### Instruction size:

1 byte for unbind[0] .. unbind[4]; 2 bytes for unbind[5], 8-bit operand; 3 bytes for unbind[6], 16-bit operand.

#### Stack effect:

-0 + 0.

#### Example: V

When dynamic binding is in effect,

#### generates:

```
PC Byte Instruction
   193
         constant[1] 1
0
1
   137
         dup
2
   24
         varbind[0] c ;; creates variable c
3
    84
         add1
4
    41
         unbind[1]
                      ;; removes variable c
   135
         return
```

Constants Vector: [c 1]

#### 3.3 Constants-Vector Retrieval Instructions

The instructions from opcode 192 to 255 push a value from the Constants Vector. See Section 2.1.1.3 [Constants Vector], page 7. Opcode 192 pushes the first entry, opcode 193, the second and so on. If there are more than 64 constants, opcode constant2 (opcode 129) is used instead.

```
constant (192-255)
```

Pushes a value from the constants vector on the evaluation stack. There are special instructions to push any one of the first 64 entries in the constants stack.

#### **Implements:**

top++; TOS <- constants\_vector[i] where i is the value of the instruction operand.

#### **Instruction size:**

1 byte

#### Stack effect:

-0 + 1.

defun n3(n)

### Example:

```
generates:

PC Byte Instruction

0 193 constant[1] +

1 8 varref[0] n
```

(+ n 10 11 12))

2 194 constant[2] 10 3 195 constant[3] 11

4 196 constant[4] 12

5 36 call[4] 6 135 return

Constants Vector: [n + 10 11 12]

## constant2 (129)

## constant2 (129)

Pushes a value from the constants vector on the evaluation stack. Although there are special instructions to push any one of the first 64 entries in the constants stack, this instruction is needed to push a value beyond one the first 64 entries.

#### **Implements:**

```
top++; TOS <- constants_vector[i] where i is the value of the instruction operand.
```

**Operand:** a 16-bit index into the constants vector.

```
Instruction size:
```

3 bytes

#### Stack effect:

-0 + 1.

#### **Example:**

```
(defun n64(n))
 (+ n 0 1 2 3 .. 64))
generates:
PC
  Byte
          Instruction
0
    193
          constant[1] +
1
          varref[0] n
      8
 2
   194
          constant[2] 0
3
   195
          constant[3] 1
4
   196
          constant[4] 2
[...]
63 255
          constant[63] 61
          constant2 [64] 62
64
   129
          64
67
    129
          constant2 [65] 63
          65
          constant2 [66] 64
70
    129
          66
           0
73
          call [66]
     38
          66
75
    135
          return
```

Constants Vector: [n + 0 1 2 .. 61 62 63 64]

## 3.4 Exception-Handling Instructions

```
pophandler (48)
Implements:
          Removes last condition pushed by pushconditioncase
Generated via:
          condition-case
Instruction size:
          1 byte
Stack effect:
          -0+0.
Added in: Emacs 24.4. See Section 4.7 [Emacs 24], page 142.
Example:
           (defun pushconditioncase-eg()
             (condition-case nil
              5
               (one-error 6)
               (another-error 7)))
          generates:
          PC Byte Instruction
           0
              192
                     constant[0] (another-error)
               49
                     pushconditioncase [16]
                     16
                     constant[1] (one-error)
              193
           5
               49
                     pushconditioncase [12]
                     12
              194
                     constant[2] 5
           8
           9
               48
                     pophandler
          10
               48
                     pophandler
          11 135
                     return
          12
               48
                     pophandler
          13 136
                     discard
          14 195
                     constant[3] 6
          15 135
                     return
              136
                     discard
          16
          17
              196
                     constant[4] 7
              135
          18
                     return
          Constants Vector: [(another-error) (one-error) 5 6 7]
```

## pushconditioncase (49)

## pushconditioncase (49)

```
Implements:
```

Pops the TOS which is some sort of condition to test on and registers that. If any of the instructions errors with that condition, a jump to the operand occurs.

```
Operand:
          16-bit PC address
Instruction size:
          3 bytes
Stack effect:
          -1 + 0.
Added in: Emacs 24.4. See Section 4.7 [Emacs 24], page 142.
Example:
          (defun pushconditioncase-eg()
            (condition-case nil
               (one-error 6)
               (another-error 7)))
          generates:
          PC Byte Instruction
                     constant[0] (another-error)
           0
              192
               49
                     pushconditioncase [16]
                     16
              193
                     constant[1] (one-error)
           4
           5
               49
                     pushconditioncase [12]
                     12
                      0
                     constant[2] 5
           8
              194
           9
               48
                     pophandler
          10
                     pophandler
               48
          11 135
                     return
          12
               48
                     pophandler
          13
              136
                     discard
          14 195
                     constant[3] 6
          15
              135
                     return
          16
              136
                     discard
          17
              196
                     constant[4] 7
              135
          18
                     return
```

Constants Vector: [(another-error) (one-error) 5 6 7]

# pushcatch (50)

pushcatch (50)

## 3.5 Control-Flow Instructions

```
goto (130)
```

### Implements:

Jump to label given in the 16-bit operand

#### Generated via:

while and various control-flow constructs

**Operand:** 16-bit PC address

#### Instruction size:

3 bytes

### Stack effect:

$$-0 + 0$$

Example: (defun goto-eg(n) (while (n) 1300)) generates:

Constants Vector: [n]

## goto-if-nil (131)

```
goto-if-nil (131)
```

### Implements:

Jump to label given in the 16-bit operand if TOS is nil. In contrast to goto-if-nil-else-pop, the test expression, TOS, is always popped.

#### Generated via:

if with "else" clause and various control-flow constructs

**Operand:** 16-bit PC address

#### Instruction size:

3 bytes

#### Stack effect:

-1 + 0

Example: (defun goto-if-nil-eg(n) (if (n) 1310 1311)) generates:

```
PC Byte Instruction
0
   192
          constant[0] n
          call[0]
 1
    32
 2
   131
          goto-if-nil [9]
           0
 5
   193
          constant[1] 1310
   130
          goto [10]
          10
          0
          constant[2] 1311
   194
9
10
   135
         return
```

Constants Vector: [n 1310 1311]

## goto-if-not-nil (132)

```
goto-if-not-nil (132)
```

### Implements:

Jump to label given in the 16-bit operand if TOS is not nil. In contrast to goto-if-not-nil-else-pop, the test expression, TOS, is always popped.

#### Generated via:

or inside an if with optimization and various control-flow constructs

**Operand:** 16-bit PC address

#### Instruction size:

3 bytes

#### Stack effect:

-1 + 0

Example: With bytecode optimization, (defun goto-if-not-nil-eg(n) (if (or (n) (n)) 1320)) generates:

```
PC Byte Instruction
   192
          constant[0] n
1
    32
          call[0]
 2
   132
          goto-if-not-nil [10]
          10
   192
          constant[0] n
5
6
    32
          call[0]
7
          goto-if-nil-else-pop [11]
   133
          11
          constant[1] 1320
10
   193
11
   135
          return
```

Constants Vector: [n 1320]

Note the change in opcode when bytecode optimization is not performed.

### goto-if-nil-else-pop (133)

### goto-if-nil-else-pop (133)

#### Implements:

Jump to label given in the 16-bit operand if TOS is nil; otherwise pop the TOS, the tested condition. This allows the test expression, nil, to be used again on the branch as the TOS.

#### Generated via:

cond, if and various control-flow constructs

**Operand:** 16-bit PC address

#### Instruction size:

3 bytes

#### Stack effect:

$$\phi(0,-1)+0$$

Example: (defun goto-if-nil-else-pop-eg(n) (cond ((n) 1330))) generates:

```
PC Byte Instruction
0
   192
         constant[0] n
1
    32
         call[0]
         goto-if-nil-else-pop [6]
   133
          6
         constant[1] 1330
5
   193
   135
6
         return
```

Constants Vector: [n 1330]

### goto-if-not-nil-else-pop (134)

### goto-if-not-nil-else-pop (134)

#### **Implements:**

Jump to label given in the 16-bit operand if TOS is not nil; otherwise pop TOS, the tested condition. This allows the tested expression on TOS to be used again when the jump is taken.

#### Generated via:

cond, if and various control-flow constructs

**Operand:** 16-bit PC address

Instruction size:

3 bytes

10

11

193

135

Stack effect:

$$\phi(0,-1)+0$$

#### Example:

```
(if (or (n) (n))
    1340))
generates:
PC Byte Instruction
0
   192
          constant[0] n
1
    32
          call[0]
2
   134
          goto-if-not-nil-else-pop [7]
           7
           0
   192
          constant[0] n
5
6
    32
          call[0]
          goto-if-nil-else-pop [11]
7
   133
          11
```

constant[1] 1340

(defun goto-if-not-nil-else-pop-eg(n)

Constants Vector: [n 1340]

return

Note the change in opcode when bytecode optimization is performed.

## return (135)

### return (135)

#### Implements:

Return from function. This is the last instruction in a function's bytecode sequence. The top value on the evaluation stack is the return value.

Generated via:

lambda

Instruction size:

1 byte

Stack effect:

-1 + 0

Example: (defun return-eg(n) 1350) generates:

PC Byte Instruction

0 192 constant[0] 1350

1 135 return

Constants Vector: [1350]

# switch (135)

### switch (135)

Jumps to entry in a jumptable

#### Implements:

Jumps to entry in a jumptable

#### Generated via:

??

#### Instruction size:

1 byte

#### Stack effect:

$$-2 + 0$$

Added in: Emacs 26.1

Example: 3

#### 3.6 Function-Call Instructions

These instructions use up one byte, and are followed by the next instruction directly. They are equivalent to calling an Emacs Lisp function with a fixed number of arguments: the arguments are popped from the stack, and a single return value is pushed back onto the stack.

#### 3.6.1 Lisp Function Instructions

These instructions correspond to general functions which are not specific to Emacs; common cases are usually inlined for speed by the bytecode interpreter.

```
symbolp (57)
```

Call symbolp.

**Implements:** 

TOS <- (symbolp TOS).

Generated via:

symbolp.

Instruction size:

1 byte

Stack effect:

-1 + 1.

Example:

When lexical binding is in effect, (defun symbolp-eg(n) (symbolp n)) generates:

PC Byte Instruction

0 137 dup

1 57 symbolp

# consp (58)

Stack effect:

-1 + 1.

Example: When lexical binding is in effect, (defun consp-eg(n) (consp n)) generates:

PC Byte Instruction 0 137 dup 1 58 consp 2 135 return

# stringp (59)

Example: When lexical binding is in effect, (defun stringp-eg(n) (stringp n)) generates:

PC Byte Instruction 0 137 dup 1 59 stringp 2 135 return

# listp (60)

1

-1 + 1.

**Example:** When lexical binding is in effect, (defun listp-eg(n) (listp n)) generates:

PC Byte Instruction
0 137 dup
1 60 listp
2 135 return

# eq (61)

```
eq(61)
```

Call eq.

Implements:

Generated via:

binary eq.

Instruction size:

1 byte

Stack effect:

$$-2 + 1$$
.

Example: When lexical binding is in effect, (defun eq-eg(a b) (eq a b)) generates:

PC Byte Instruction
0 1 stack-ref[1]
1 1 stack-ref[1]

2 61 eq

## memq (62)

```
memq(62)
```

Call memq.

Implements:

Generated via:

binary memq.

Instruction size:

1 byte

Stack effect:

$$-2 + 1$$
.

When lexical binding is in effect, (defun memq-eg(a b) (memq a b)) generates: Example:

> PC Byte Instruction 0 1 stack-ref[1] stack-ref[1] 1 1 2 62 memq 3 135

return

# not (63)

```
not (63)
```

Call not.

Implements:

Generated via:

unary not.

Instruction size:

1 byte

Stack effect:

$$-1 + 1$$
.

Example: When lexical binding is in effect, (defun not-eg(a) (not a)) generates:

PC Byte Instruction

0 137 dup

1 63 not

# symbol-value (74)

```
symbol-value (74)
```

 ${\rm Call} \ {\tt symbol-value}.$ 

Implements:

TOS <- (symbol-value TOS).

Generated via:

symbol-value.

Instruction size:

1 byte

Stack effect:

-1 + 1.

Example: When lexical binding is in effect, (defun symbol-value-eg(a) (symbol-value

a)) generates:

PC Byte Instruction

0 137 dup

1 74 symbol-value

## symbol-function (75)

```
symbol-function (75)
```

 ${\rm Call} \ {\tt symbol-function}.$ 

Implements:

TOS <- (symbol-function TOS).

Generated via:

symbol-function.

Instruction size:

1 byte

Stack effect:

-1 + 1.

When lexical binding is in effect, (defun symbol-function-eg(a) (symbol-Example: function a)) generates:

PC Byte Instruction

0 137 dup

symbol-function 75

# set (76)

```
set (76)
```

Call set.

Implements:

$$S[1] \leftarrow (set S[1] TOS); top--.$$

Generated via:

set.

Instruction size:

1 byte

Stack effect:

$$-2 + 1$$
.

Example: When lexical binding is in effect, (defun set-eg(a b) (set a b)) generates:

PC Byte Instruction
0 1 stack-ref[1]
1 1 stack-ref[1]

2 76 set 3 135 return

# fset (77)

```
fset (77)
```

Call fset.

Implements:

$$S[1] \leftarrow (fset S[1] TOS); top--.$$

Generated via:

binary fset.

Instruction size:

1 byte

Stack effect:

$$-2 + 1$$
.

Example: When lexical binding is in effect, (defun fset-eg(a b) (fset a b)) generates:

PC Byte Instruction
0 1 stack-ref[1]
1 1 stack-ref[1]

2 77 fset3 135 return

# get (78)

```
get (78)
```

Call get.

Implements:

Generated via:

binary get.

Instruction size:

1 byte

Stack effect:

$$-2 + 1$$
.

Example: When lexical binding is in effect, (defun get-eg(a b) (get a b)) generates:

PC Byte Instruction
0 1 stack-ref[1]
1 1 stack-ref[1]

2 78 get3 135 return

## equal (154)

```
equal (154)
```

Call equal.

Implements:

Generated via:

binary equal.

Instruction size:

1 byte

Stack effect:

$$-2 + 1$$
.

Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

Example: When lexical binding is in effect, (defun equal-eg(a b) (equal a b)) gener-

ates:

PC Byte Instruction
0 1 stack-ref[1]
1 1 stack-ref[1]
2 154 equal
3 135 return

## member (157)

```
member (157)
Call member.
Implements:
          S[1] <- (member S[1] TOS); top--.
Generated via:
          member.
Instruction size:
          1 byte
Stack effect:
           -2 + 1.
          When lexical binding is in effect, (defun member-eg(a b) (member a b)) gen-
Example:
          erates:
          PC Byte Instruction
              1
                     stack-ref[1]
              1
                    stack-ref[1]
            2 157
                     member
            3 135
                     return
```

## assq (158)

```
assq (158)
```

Call assq.

Implements:

Generated via:

binary assq.

Instruction size:

1 byte

Stack effect:

$$-2 + 1$$
.

Example: When lexical binding is in effect, (defun assq-eg(a b) (assq a b)) generates:

PC Byte Instruction
0 1 stack-ref[1]
1 1 stack-ref[1]

2 158 assq3 135 return

# number (167)

Example:

```
numberp (167)
{\rm Call} \ {\tt numberp}.
Implements:
            TOS <- (numberp TOS).
Generated via:
            numberp.
Instruction size:
            1 byte
Stack effect:
            -1 + 1.
Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.
            When lexical binding is in effect, (defun numberp-eg(a) (numberp a)) gener-
```

PC Byte Instruction

0 137 dup 1 167 numberp

ates:

# integerp (168)

PC Byte Instruction

0 137 dup

erates:

1 168 integerp 2 135 return

#### 3.6.2 List Function Instructions

These instructions correspond to general functions which are not specific to Emacs; common cases are usually inlined for speed by the bytecode interpreter.

#### nth (56)

Call nth with two stack arguments.

**Implements:** 

Generated via:

nth.

**Instruction size:** 

1 byte

Stack effect:

$$-2 + 1$$
.

Example: When lexical binding is in effect, (defun nth-eg(1) (nth 560 1)) generates:

PC Byte Instruction

0 192 constant[0] 560

1 1 stack-ref[1]

2 56 nth

3 135 return

Constants Vector: [560]

# car(64)

```
car (64)
```

Call car with one stack argument.

Implements:

Generated via:

car.

Instruction size:

1 byte

Stack effect:

$$-1 + 1$$
.

**Example:** When lexical binding is in effect, (defun car-eg(1) (car 1)) generates:

PC Byte Instruction

0 137 dup

1 64 car

# cdr (65)

```
cdr(65)
```

Call  $\operatorname{\mathsf{cdr}}$  with one stack argument.

Implements:

Generated via:

cdr.

Instruction size:

1 byte

Stack effect:

$$-1 + 1$$
.

**Example:** When lexical binding is in effect, (defun cdr-eg(1) (cdr 1)) generates:

PC Byte Instruction

0 137 dup

1 65 cdr

# cons (66)

```
cons (66)
```

Call cons with two stack arguments.

Implements:

Generated via:

cons.

Instruction size:

1 byte

Stack effect:

-2 + 1.

Example: (defun cons-eg() (cons 'a 'b)) generates:

PC Byte Instruction
0 192 constant[0] a
1 193 constant[1] b
2 66 cons

3 135 return

Constants Vector: [a b]

# list1 (67)

```
list1 (67)
Call list with TOS.
Implements:
          TOS <- (list TOS).
Generated via:
          list.
Instruction size:
          1 byte
Stack effect:
          -1 + 1.
Example: (defun list1-eg() (list 'a)) generates:
          PC Byte Instruction
           0 192
                   constant[0] a
           1
              67
                    list1
           2 135
                   return
```

Constants Vector: [a]

Call list with TOS.

# list2 (68)

```
list2 (68)
```

Call list with two stack items.

Implements:

Generated via:

list.

Instruction size:

1 byte

Stack effect:

-2 + 1.

Example: (defun list2-eg() (list 'a 'b)) generates:

PC Byte Instruction 0 192 constant[0] a 1 193 constant[1] b 2 68 list2

2 68 list2 3 135 return

Constants Vector: [a b]

# list3 (69)

```
list3 (69)
```

Call list with three stack items.

**Implements:** 

$$S[2] \leftarrow (list S[2] S[1] TOS); top -= 2.$$

Generated via:

list

Instruction size:

1 byte

Stack effect:

$$-3 + 1$$
.

Example: (defun list3-eg() (list 'a 'b 'c)) generates:

```
PC Byte Instruction
0 192 constant[0] a
1 193 constant[1] b
2 194 constant[2] c
3 69 list3
4 135 return
```

Constants Vector: [a b c]

# list4 (70)

```
list4 (70)
```

Call list with four stack items.

**Implements:** 

$$S[3] \leftarrow (list S[3] S[2] S[1] TOS); top -= 2.$$

Generated via:

list.

Instruction size:

1 byte

Stack effect:

-4 + 1.

Example: (defun list4-eg() (list 'a 'b 'c 'd)) generates:

PC Byte Instruction
0 192 constant[0] a
1 193 constant[1] b
2 194 constant[2] c
3 195 constant[3] d
4 70 list4
5 135 return

Constants Vector: [a b c d]

### listN (175)

#### listN (175)

Call list on up to 255 items. Note that there are special instructions for the case where there are 1 to 4 items in the list.

#### **Implements:**

```
S[n-1] \leftarrow (list S[n-1] S[n-2] \dots TOS); top -= (n-1) where n is the value of the operand.
```

#### Generated via:

list.

**Operand:** 8-bit number of items in list

#### Instruction size:

2 bytes

#### Stack effect:

-n+1 where n is the value of the instruction operand.

Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

Example: (defun listN-eg() (list 'a 'b 'c 'd 'e)) generates:

```
PC
   Byte Instruction
 0
   192
          constant[0] a
   193
          constant[1] b
 1
 2 194
          constant[2] c
 3 195
         constant[3] d
 4 196
          constant[4] e
 5
   175
          listN [5]
           5
   135
          return
```

Constants Vector: [a b c d e]

# length (71)

2

135

```
length (71)
Call length with one stack argument.
Implements:
          TOS <- (length TOS).
Generated via:
          length.
Instruction size:
          1 byte
Stack effect:
          -1 + 1.
          (defun length-eg() (length '(a b))) generates:
Example:
          PC Byte Instruction
                    constant[0] (a b)
           0 192
           1
               71
                    length
```

return

Constants Vector: [(a b)]

# aref (72)

```
aref (72)
```

Call aref with two stack arguments.

Implements:

Generated via:

aref.

Instruction size:

1 byte

Stack effect:

-2 + 1.

Example: (defun aref-eg() (aref '[720 721 722] 0)) generates:

PC Byte Instruction

0 192 constant[0] [720 721 722]

1 193 constant[1] 0

2 72 aref3 135 return

Constants Vector: [[720 721 722] 0]

## aset (73)

```
aset (73)
```

Call aset with three stack arguments.

**Implements:** 

$$S[2] \leftarrow (aset S[2] S[1] TOS); top-=2.$$

Generated via:

aset.

Instruction size:

1 byte

Stack effect:

-2 + 1.

Example: (defun aset-eg() (aset array-var 0 730)) generates:

PC Byte Instruction

0 8 varref[0] array-var

1 193 constant[1] 0

2 194 constant[2] 730

3 73 aset

4 135 return

Constants Vector: [array-var 0 730]

### nthcdr (155)

2 155

3 135

```
nthcdr (155)
Call nthcdr with two stack arguments.
Implements:
          S[1] <- (nthcdr S[1] TOS); top --.
Generated via:
          nthcdr.
Instruction size:
          1 byte
Stack effect:
           -2 + 1.
Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.
Example:
          (defun nthcdr-eg() (nthcdr '(1550 1551 1552) 2)) generates:
          PC Byte Instruction
           0 192
                     constant[0] (1550 1551 1552)
            1 193
                    constant[1] 2
```

Constants Vector: [(1550 1551 1552) 2]

nthcdr

return

## elt (156)

```
elt (156)
```

Call elt with two stack arguments.

**Implements:** 

$$S[1] \leftarrow (elt S[1] TOS); top --.$$

Generated via:

elt.

Instruction size:

1 byte

Stack effect:

-2 + 1.

Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

**Example:** (defun elt-eg() (elt '(1560 1561 1562) 2)) generates:

PC Byte Instruction

0 192 constant[0] (1560 1561 1562)

1 193 constant[1] 2

2 156 elt
3 135 return

Constants Vector: [(1560 1561 1562) 2]

## nreverse (159)

```
nreverse (159)
```

Call nreverse with one stack argument.

Implements:

Generated via:

nreverse.

Instruction size:

1 byte

Stack effect:

$$-1 + 1$$
.

Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

Example: (defun nreverse-eg() (nreverse '(1590 1591))) generates:

PC Byte Instruction

0 192 constant[0] (1590 1591)

1 159 nreverse2 135 return

Constants Vector: [(1590 1591)]

### setcar (160)

```
setcar (160)
```

Call setcar with two stack arguments.

**Implements:** 

Generated via:

setcar.

Instruction size:

1 byte

Stack effect:

-2 + 1.

Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

Example: With lexical binding in effect, (defun setcar-eg(1) (setcar 1 1600))) gen-

erates:

PC Byte Instruction

0 137 dup

1 192 constant[0] 1600

2 160 setcar3 135 return

Constants Vector: [1600]

## setcdr (161)

```
setcdr (161)
```

Call setcdr with two stack arguments.

**Implements:** 

Generated via:

setcdr.

Instruction size:

1 byte

Stack effect:

-2 + 1.

Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

Example: With lexical binding in effect, (defun setcdr-eg(1) (setcdr 1 1610))) gen-

erates:

PC Byte Instruction

0 137 dup

1 192 constant[0] 1610

2 161 setcdr
3 135 return

Constants Vector: [1610]

## car-safe (162)

```
car-safe (162)
```

Call car-safe with one argument.

Implements:

TOS <- (car-safe TOS).

Generated via:

car-safe.

Instruction size:

1 byte

Stack effect:

-1 + 1.

Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

Example: With lexical binding in effect, (defun car-safe-eg(1) (car-safe 1)) gener-

ates:

PC Byte Instruction

0 137 dup

1 162 car-safe

2 135 return

## cdr-safe (163)

```
cdr-safe (163)
```

Call cdr-safe with one stack argument.

Implements:

Generated via:

cdr-safe.

Instruction size:

1 byte

Stack effect:

$$-1 + 1$$
.

Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

Example: With lexical binding in effect, (defun cdr-safe-eg(1) (cdr-safe 1)) gener-

ates:

PC Byte Instruction

0 137 dup

1 163 cdr-safe

2 135 return

# nconc (164)

```
nconc (164)
```

Call nconc with two stack arguments.

Implements:

Generated via:

nconc.

Instruction size:

1 byte

Stack effect:

$$-2 + 1$$
.

Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

Example: With lexical binding in effect, (defun nconc-eg(a b) (nconc a b)) generates:

PC Byte Instruction
0 1 stack-ref[1]
1 1 stack-ref[1]

2 164 nconc3 135 return

#### 3.6.3 Arithmetic Function Instructions

These instructions correspond to general functions which are not specific to Emacs; common cases are usually inlined for speed by the bytecode interpreter.

```
sub1 (83)
```

Call 1-.

Implements:

Generated via:

1-.

Instruction size:

1 byte

Stack effect:

-1 + 1.

Example: When lexical binding is in effect, (defun sub1-eg(n) (1-n)) generates:

PC Byte Instruction

0 137 dup

1 83 sub1

2 135 return

# add1 (84)

```
add1 (84)
```

Call 1+.

Implements:

Generated via:

unary -.

Instruction size:

1 byte

Stack effect:

-1 + 1.

Example: When lexical binding is in effect, (defun add1-eg(n) (1+ n)) generates:

PC Byte Instruction

0 137 dup

1 84 add1

2 135 return

# eqlsign (85)

```
eqlsign (85)
Call = .
Implements:
           S[1] \leftarrow (= S[1] TOS); top--.
Generated via:
           binary =.
Instruction size:
           1 byte
Stack effect:
           -2 + 1.
          When dynamic binding is in effect, (defun eqlsign-eg(a b) (= a b)) gener-
Example:
           ates:
           PC Byte Instruction
                     varref[0] a
            1
                 9
                    varref[1] b
            2
                85
                      eqlsign
                      return
            3
               135
```

Constants Vector: [a b]

# gtr (86)

```
gtr(86)
```

Call >.

Implements:

Generated via:

>.

Instruction size:

1 byte

Stack effect:

$$-2 + 1$$
.

Example: When lexical binding is in effect, (defun gtr-eg(a b) (> a b)) generates:

PC Byte Instruction
0 1 stack-ref[1]
1 1 stack-ref[1]

2 86 gtr 3 135 return

# lss (87)

```
lss(87)
```

 $\operatorname{Call} <.$ 

Implements:

Generated via:

<.

Instruction size:

1 byte

Stack effect:

-2 + 1.

Example: When dynamic binding is in effect, (defun lss-eg(a b) (< a b)) generates:

PC Byte Instruction

0 8 varref[0] a

1 9 varref[1] b

2 87 lss

3 135 return

Constants Vector: [a b]

# leq (88)

3 135

return

Constants Vector: [a b]

```
leq (88)
Call <=.
Implements:
          S[1] <- (<= S[1] TOS); top--.
Instruction size:
           1 byte
Generated via:
Instruction size:
           1 byte
Stack effect:
           -2 + 1.
          When dynamic binding is in effect, (defun leq-eg(a b) (<= a b)) generates:
Example:
           PC Byte Instruction
            0
                 8
                     varref[0] a
                     varref[1] b
            1
                 9
            2
               88
                     leq
```

# geq (89)

```
geq (89)
```

Call >=.

Implements:

$$S[1] \leftarrow (>= S[1] TOS); top--.$$

Instruction size:

1 byte

Generated via:

>=

Instruction size:

1 byte

Stack effect:

$$-2 + 1$$
.

Example: When lexical binding is in effect, (defun geq-eg(a b) (>= a b)) generates:

PC Byte Instruction
0 1 stack-ref[1]
1 1 stack-ref[1]

2 89 geq3 135 return

# diff (90)

```
diff(90)
```

Call binary -.

Implements:

$$S[1] \leftarrow (-S[1] TOS); top--.$$

Generated via:

binary -.

Instruction size:

1 byte

Instruction size:

1 byte

Stack effect:

$$-2 + 1$$
.

Example: When lexical binding is in effect, (defun diff-eg(a b) (- a b)) generates:

PC Byte Instruction
0 1 stack-ref[1]
1 1 stack-ref[1]
2 90 diff

2 90 diff3 135 return

# negate (91)

```
negate (91)
Call unary -.
Implements:
           TOS <- (- TOS).
Generated via:
           unary -.
Instruction size:
           1 byte
Instruction size:
           1 byte
Stack effect:
           -1 + 1.
          When lexical binding is in effect, (defun negate-eg(a) (- a)) generates:
Example:
           PC Byte Instruction
            0
                 8
                     varref[0] a
            1
                91
                     negate
            2
              135
                     return
           Constants Vector: [a]
```

# plus (92)

```
plus (92)
Call unary +.
Implements:
          S[1] <- (+ S[1] TOS); top--.
Generated via:
Instruction size:
          1 byte
Stack effect:
           -2 + 1.
          When dynamic binding is in effect, (defun plus-eg(n) (+ n n)) generates:
Example:
          PC
              Byte Instruction
           0
               8
                     varref[0] n
            1 137
                     dup
            2
               92
                     plus
            3
              135
                     return
          Constants Vector: [n]
```

# mult (95)

```
mult (95)
Call *.
Implements:
           S[1] <- (* S[1] TOS); top--.
Generated via:
Instruction size:
           1 byte
Stack effect:
           -2 + 1.
Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.
           When dynamic binding is in effect, (defun mult-eg(n) (* n n)) generates:
Example:
              Byte Instruction
           PC
            0
                  8
                      varref[0] n
            1
               137
                      dup
            2
                95
                      mult
            3
               135
                      return
```

Constants Vector: [n]

# $\max (93)$

```
\max (93)
Call max.
Implements:
           S[1] \leftarrow (max S[1] TOS); top--.
Generated via:
           max.
Instruction size:
           1 byte
Stack effect:
           -2 + 1.
           When dynamic binding is in effect, (defun max-eg(a b) (max a b)) generates:
Example:
                Byte Instruction
           PC
                  8
                      varref[0] a
                      varref[1] b
            1
                  9
            2
                93
                      max
               135
                      return
```

Constants Vector: [a b]

# min (94)

```
min (94)
```

 $\operatorname{Call}\, \operatorname{\mathtt{min}}.$ 

Implements:

 $TOS \leftarrow (min(S[1] TOS).$ 

Generated via:

binary min.

Instruction size:

1 byte

Stack effect:

-2 + 1.

Example: When dynamic binding is in effect, (defun min-eg(a b) (min a b)) generates:

PC Byte Instruction
0 8 varref[0] a
1 9 varref[1] b

94 min3 135 return

Constants Vector: [a b]

## quo (165)

```
quo(165)
Call /.
Implements:
          S[1] <- (/ S[1] TOS); top--.
Generated via:
          /.
Instruction size:
          1 byte
Stack effect:
          -2 + 1.
          When dynamic binding is in effect, (defun min-quo(a b) (/ a b)) generates:
Example:
          PC Byte Instruction
           0
               8
                    varref[0] a
                   varref[1] b
           1
                9
           2 165
                    quo
              135
                    return
          Constants Vector: [a b]
```

# rem (166)

 $\textbf{Added in:} \quad \text{Emacs 19.34. See Section 4.2 [Emacs 19], page 138. }$ 

Example: When lexical binding is in effect, (defun rem-eg(a b) (% a b)) generates:

PC Byte Instruction
0 1 stack-ref[1]
1 1 stack-ref[1]
2 166 rem
3 135 return

#### 3.6.4 String Function Instructions

These instructions correspond to general functions which are not specific to Emacs; the bytecode interpreter calls the corresponding C function for them.

```
substring (79)
```

Call substring with three stack arguments.

#### **Implements:**

$$S[2] \leftarrow (substring S[2] S[1] TOS); top=2.$$

Generated via:

substring.

Instruction size:

1 byte

Stack effect:

$$-2 + 1$$
.

Example: (defun substring-eg() (substring "abc" 0 2)) generates:

```
PC Byte Instruction
0 192 constant[0] "abc"
1 193 constant[1] 0
2 194 constant[2] 2
3 79 substring
4 135 return
```

Constants Vector: ["abc" 0 2]

## concat2 (80)

```
concat2 (80)
```

Call concat with two stack arguments.

**Implements:** 

Generated via:

concat.

Instruction size:

1 byte

Stack effect:

$$-2 + 1$$
.

Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

Example: (defun concat2-eg() (concat "a" "b")) generates:

PC Byte Instruction
0 192 constant[0] "a"
1 193 constant[1] "b"

2 80 concat23 135 return

Constants Vector: ["a" "b"]

## concat3 (81)

```
concat3 (81)
```

Call concat with three stack arguments.

```
Implements:
```

Generated via:

concat.

Instruction size:

1 byte

Stack effect:

$$-2 + 1$$
.

Example: (defun concat3-eg() (concat "a" "b" "c")) generates:

```
PC Byte Instruction
0 192 constant[0] "a"
1 193 constant[1] "b"
2 194 constant[2] "c"
3 81 concat3
4 135 return
```

Constants Vector: ["a" "b" "c"]

## concat4 (82)

```
concat4 (82)
```

Call concat with four stack stack arguments.

```
Implements:
```

$$S[3] \leftarrow (concat S[3] S[2] S[1] TOS); top -= 2.$$

Generated via:

concat.

Instruction size:

1 byte

Stack effect:

-4 + 1.

Example: (defun concat4-eg() (concat "a" "b" "c" "d")) generates:

```
PC Byte Instruction
0 192 constant[0] "a"
1 193 constant[1] "b"
2 194 constant[2] "c"
3 195 constant[3] "d"
4 82 concat4
5 135 return
```

Constants Vector: ["a" "b" "c" "d"]

#### concatN (174)

#### concatN (174)

Call concat on up to 255 stack arguments. Note there are special instructions for the case where there are 2 to 4 items to concatenate.

#### **Implements:**

$$S[n-1] \leftarrow (concat S[n-1] S[n-2] \dots TOS); top -= (n-1).$$

#### Generated via:

concat.

**Operand:** 8-bit number of items in concat

#### Instruction size:

2 bytes

#### Stack effect:

-n+1 where n is the value of the instruction operand.

Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

Example: (defun concatN-eg() (concat "a" "b" "c" "d" "e")) generates:

```
PC Byte Instruction
0 192 constant[0] "a"
1 193 constant[1] "b"
2 194 constant[2] "c"
3 195 constant[3] "d"
4 196 constant[4] "e"
5 176 concatN [5]
5
7 135 return
```

Constants Vector: ["a" "b" "c" "d" "e"]

## upcase (150)

```
upcase (150)
```

Call upcase with one stack argument.

Implements:

TOS <- (upcase TOS).

Generated via:

upcase.

Instruction size:

1 byte

Stack effect:

-1 + 1.

Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

Example: (defun upcase-eg() (upcase "abc")) generates:

PC Byte Instruction

0 192 constant[0] "abc"

1 150 upcase 2 135 return

Constants Vector: ["abc"]

## downcase (151)

```
downcase (151)
```

Call downcase with one argument.

Implements:

TOS <- (downcase TOS).

Generated via:

downcase.

Instruction size:

1 byte

Stack effect:

-1 + 1.

Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

Example: (defun downcase-eg(1) (downcase "ABC")) generates:

PC Byte Instruction

0 192 constant[0] "ABC"

1 151 downcase 2 135 return

Constants Vector: ["ABC"]

### stringeqlsign (152)

```
stringeqlsign (152)
```

Call string= with two stack arguments, comparing two strings for equality.

**Implements:** 

Generated via:

string=.

Instruction size:

1 byte

Stack effect:

$$-2 + 1$$
.

Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

**Example:** With lexical binding in effect,

generates:

PC Byte Instruction

0 137 dup

1 192 constant[0] "b"

2 152 string=

3 135 return

Constants Vector: ["b"]

### stringlss (153)

```
stringlss (153)
```

Call string< with two stack arguments, comparing two strings.

Implements:

Generated via:

string<.

Instruction size:

1 byte

Stack effect:

$$-2 + 1$$
.

Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

**Example:** With lexical binding in effect,

(defun stringlss-eg(a)
 (string< a "b"))</pre>

generates:

PC Byte Instruction

0 137 dup

1 192 constant[0] "b"

2 153 string<

3 135 return

Constants Vector: ["b"]

#### 3.6.5 Emacs Buffer Instructions

```
{\tt current-buffer}\ (112)
```

Call current-buffer.

Implements:

Generated via:

current-buffer

Instruction size:

1 byte

Stack effect:

-0 + 1.

**Example:** (defun current-buffer-eg() (current-buffer)) generates:

PC Byte Instruction 0 112 current-buffer

1 135 return

# set-buffer (113)

```
set-buffer (113)
Call set-buffer with TOS.
Implements:
        TOS <- (set-buffer TOS)
Generated via:
        set-buffer
Instruction size:
        1 byte
Stack effect:
        -1 + 1.
PC Byte Instruction
        0 192 constant[0] "*scratch"
         1 113 set-buffer
        2 135 return
        Constants Vector: ["*scratch"]
```

#### save-current-buffer-1 (114)

Constants Vector: [prog 5]

```
save-current-buffer-1 (114)
Call save-current-buffer.
  Replaces older save-current-buffer. See [save-current-buffer], page 134.
Implements:
          TOS <- (save-current-buffer)</pre>
Generated via:
          save-current-buffer
Instruction size:
          1 byte
Stack effect:
          -1 + 1.
Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.
Example:
          (defun save-curent-buffer-1-eg() (save-current-buffer (prog 5)))
          generates:
          PC Byte Instruction
                   save-current-buffer
           0 114
           1 192 constant[0] prog
           2 193 constant[1] 5
           3
              33 call[1]
              41 unbind[1]
           5 135
                    return
```

### buffer-substring (123)

```
buffer-substring (123)
Call buffer-substring with two stack arguments.
Implements:
          S[1] <- (buffer-substring S[1] TOS); top--.
Generated via:
          buffer-substring.
Instruction size:
          1 byte
Stack effect:
          -2 + 1. Emacs 19.34. See Section 4.2 [Emacs 19], page 138.
          (defun buffer-substring-eg() (buffer-substring 1230 1231)) generates:
Example:
          PC Byte Instruction
           0 192 constant[0] 1230
           1 193 constant[1] 1231
           2 123 buffer-substring
```

Constants Vector: [1230 1231]

3 135 return

#### 3.6.6 Emacs Position Instructions

These instructions correspond to Emacs-specific position functions that are found in the "Positions" chapter of the Emacs Lisp Reference Manual. They are not inlined by the bytecode interpreter, but simply call the corresponding C function.

```
point (96)
```

Call point.

**Implements:** 

TOS <- (point)

Generated via:

point

Instruction size:

1 byte

Stack effect:

-0 + 1.

Added in: Emacs 18.31, renamed from dot. See Section 4.1 [Emacs 18], page 137.

Example: (defun point-eg() (point)) generates:

PC Byte Instruction

0 96 point 1 135 return

# goto-char (98)

```
goto-char (98)
```

Call goto-char with one stack argument.

Implements:

Generated via:

goto-char

Instruction size:

1 byte

Stack effect:

$$-1 + 1$$
.

Example: With lexical binding in effect, (defun goto-char-eg(n) (goto-char n)) gen-

erates:

PC Byte Instruction

0 137 dup

98 goto-char
 135 return

# point-max (100)

```
point-max (100)
```

 ${\rm Call} \ {\tt point-max}.$ 

Implements:

TOS <- (point-max)

Generated via:

point-max

Instruction size:

1 byte

Stack effect:

-0 + 1.

Added in: Emacs 18.31, renamed from dot-max. See Section 4.1 [Emacs 18], page 137.

Example: (defun point-max-eg() (point-max)) generates:

PC Byte Instruction 0 100 point-max 1 135 return

## point-min (101)

Stack effect:

-0 + 1.

1 byte

Added in: Emacs 18.31, renamed from dot-min. See Section 4.1 [Emacs 18], page 137.

Example: (defun point-min-eg() (point-min)) generates:

PC Byte Instruction 0 101 point-min 1 135 return

## forward-char (117)

```
forward-char (117)
```

Call forward-char with one stack argument.

Implements:

TOS <- (forward-char TOS)

Generated via:

forward-char

Instruction size:

1 byte

Stack effect:

-1 + 1.

Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

Example: (defun forward-char-eg() (forward-char 1)) generates:

PC Byte Instruction 0 192 constant[0] 1 1 117 forward-char

2 135 return

## forward-word (118)

```
forward-word (118)
```

Call forward-word with one stack argument.

Implements:

TOS <- (forward-word TOS)

Generated via:

forward-word

Instruction size:

1 byte

Stack effect:

-1 + 1.

Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

Example: (defun forward-word-eg() (forward-word 1)) generates:

PC Byte Instruction
0 192 constant[0] 1
1 118 forward-word

2 135 return

## forward-line (121)

```
forward-line (121)
```

Call forward-line with one stack argument.

Implements:

TOS <- (forward-line TOS)

Generated via:

forward-line

Instruction size:

1 byte

Stack effect:

-1 + 1.

Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

Example: (defun forward-line-eg() (forward-line 1)) generates:

PC Byte Instruction 0 192 constant[0] 1 1 121 forward-line

2 135 return

## skip-chars-forward (119)

```
skip-chars-forward (119)
Call skip-chars-forward with two stack arguments.
Implements:
          S[1] <- (skip-chars-forward S[1] TOS); top--.
Generated via:
          {\tt skip-chars-forward}.
Instruction size:
          1 byte
Stack effect:
          -2 + 1.
Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.
          (defun skip-chars-forward-eg() (skip-chars-forward "aeiou" 3))
Example:
          generates:
          PC Byte Instruction
           0 192 constant[0] "aeiou"
           1 193 constant[1] 3
           2 119 skip-chars-forward
           3 135
                   return
```

Constants Vector: ["aeiou" 3]

## skip-chars-backward (120)

```
skip-chars-backward (120)
Call skip-chars-backward with two stack arguments.
Implements:
          S[1] <- (skip-chars-backward S[1] TOS); top--.
Generated via:
          {\tt skip-chars-backward}.
Instruction size:
          1 byte
Stack effect:
          -2 + 1.
Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.
          (defun skip-chars-backward-eg() (skip-chars-backward "aeiou" 3))
Example:
          generates:
          PC Byte Instruction
           0 192 constant[0] "aeiou"
           1 193 constant[1] 3
           2 120 skip-chars-backward
           3 135
                   return
```

Constants Vector: ["aeiou" 3]

## narrow-to-region (125)

```
narrow-to-region (125)
```

Call narrow-to-region with two stack arguments.

**Implements:** 

Generated via:

narrow-to-region.

Instruction size:

1 byte

Stack effect:

-2 + 1.

Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

Example: (defun narrow-to-region-eg() (narrow-to-region 1250 1251)) generates:

PC Byte Instruction

0 192 constant[0] 1250

1 193 constant[1] 1251

2 125 narrow-to-region

3 135 return

Constants Vector: [1250 1251]

# widen (126)

```
widen (126)
```

 $\operatorname{Call} \, \mathtt{widen}.$ 

Implements:

TOS <- (widen)

Generated via:

widen

Instruction size:

1 byte

Stack effect:

-0 + 1.

 $\textbf{Added in:} \quad \text{Emacs 19.34. See Section 4.2 [Emacs 19], page 138. }$ 

Example: (defun widen-eg() (widen)) generates:

PC Byte Instruction

0 126 widen 1 135 return

### 3.6.7 Emacs Text Instructions

These instructions correspond to Emacs-specific text manipulation functions found in the "Text" chapter of the Emacs Lisp Reference Manual. They are not inlined by the bytecode interpreter, but simply call the corresponding C function.

### insert (99)

Call insert with one stack argument.

**Implements:** 

TOS <- (insert TOS)

Generated via:

insert

Instruction size:

1 byte

Stack effect:

-1 + 1.

Example: With lexical binding in effect, (defun insert-eg(n) (insert n)) generates:

PC Byte Instruction

0 137 dup

1 99 insert

## insertN (99)

### insertN (99)

Call insert on up to 255 stack arguments. Note there is a special instruction when there is only one stack argument.

**Implements:** 

$$S[n-1] \leftarrow (insert S[n-1] S[n-2] \dots TOS); top -= (n-1).$$

Generated via:

insert

**Operand:** 8-bit number of items in concat

Instruction size:

2 bytes

Stack effect:

-n+1 where n is the value of the instruction operand.

Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

Example: With lexical binding in effect, (defun insertN-eg(abc) (insert abc))

generates:

PC Byte Instruction
0 2 stack-ref[2]
1 2 stack-ref[2]
2 2 stack-ref[2]
3 177 insertN [3]
3

# char-after (102)

```
char-after (102)
```

Call char-after with one stack argument.

Implements:

Generated via:

char-after

Instruction size:

1 byte

Stack effect:

$$-1 + 1$$
.

 $\begin{tabular}{ll} \bf Example: & (defun char-after-eg() (char-after)) \ generates: \\ \end{tabular}$ 

PC Byte Instruction
0 192 constant[0] nil
1 102 char-after
2 135 return

# following-char (103)

# preceding-char (104)

## current-column (105)

# eolp (108)

return

# eobp (109)

eobp

return

0 109

# bolp (110)

return

# bobp (111)

bobp

return

0 111

## delete-region (124)

```
delete-region (124)
```

Call delete-region with two stack arguments.

Call delete-region with two stack arguments.

Implements:

Generated via:

delete-region.

Instruction size:

1 byte

Stack effect:

-2 + 1.

Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

Example: (defun delete-region-eg() (delete-region 1240 1241)) generates:

PC Byte Instruction

0 192 constant[0] 1240

1 193 constant[1] 1241

2 124 delete-region

3 135 return

Constants Vector: [1240 1241]

## end-of-line (127)

```
end-of-line (127)
```

Call end-of-line with one stack argument.

Implements:

(end-of-line TOS; top--

Generated via:

delete-region.

Instruction size:

1 byte

Stack effect:

-1 + 0 - .

Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

Example: (defun end-of-line-eg() (end-of-line)) generates:

PC Byte Instruction 0 192 constant[0] nil 1 127 end-of-line

2 135 return

### 3.6.8 Emacs Misc Function Instructions

These instructions correspond to miscellaneous Emacs-specific functions. They are not inlined by the bytecode interpreter, but simply call the corresponding C function.

```
char-syntax (122)
```

Call char-syntax with one stack argument.

**Implements:** 

Generated via:

char-syntax

Instruction size:

1 byte

Stack effect:

$$-1 + 1$$
.

Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

Example: (defun char-syntax-eg() (char-syntax ?a)) generates:

PC Byte Instruction 0 192 constant[0] 97 1 122 char-syntax 2 135 return

## save-excursion (138)

```
save-excursion (138)
```

Make a binding recording buffer, point, and mark.

This instruction manipulates the special-bindings stack by creating a new binding when executed. It needs to be balanced with unbind instructions.

#### **Implements:**

```
(save-excursion).
```

Generated via:

save-excursion

Instruction size:

1 byte

Stack effect:

-0 + 0.

Example: When lexical binding is in effect, (defun save-excursion-eg() (save-excursion 1380)) generates:

PC Byte Instruction
0 138 save-excursion
1 192 constant[0] 1380
2 41 unbind[1]
3 135 return

## set-marker (147)

```
set-marker (147)
```

Call set-marker with three stack arguments.

**Implements:** 

$$S[2] \leftarrow (set-marker S[2] S[1] TOS); top -= 2.$$

Generated via:

set-marker

Instruction size:

1 byte

Stack effect:

$$-3 + 1$$
.

Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

Example: When lexical binding is in effect, (defun set-marker-eg(marker position)

(set-marker marker position)) generates:

PC Byte Instruction
0 1 stack-ref[1]
1 1 stack-ref[1]
2 192 constant[0] nil
3 147 set-marker
4 135 return

# match-beginning (148)

```
match-beginning (148)
Call match-beginning with one stack argument.

Implements:
```

TOS <- (match-beginning TOS)

Generated via:

match-beginning

Instruction size:

1 byte

Stack effect:

-1 + 1.

Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

Example: (defun match-beginning-eg() (match-beginning 1)) generates:

PC Byte Instruction 0 192 constant[0] 1 1 148 match-beginning

2 135 return

## match-end (149)

```
match-end (149)
```

Call match-end with one stack argument.

Implements:

TOS <- (match-end TOS)

Generated via:

match-end

Instruction size:

1 byte

Stack effect:

-1 + 1.

Added in: Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

Example: (defun match-end-eg() (match-end 1)) generates:

PC Byte Instruction
0 192 constant[0] 1
1 148 match-end
2 135 return

## 3.7 Stack-Manipulation Instructions

### discard (136)

Discard one value from the stack.

#### **Implements:**

top--

### Instruction size:

1 byte

#### Generated via:

Function calls that do not use the returned value; the end of let forms in lexical binding to remove locally-bound variables.

### Stack effect:

-1 + 0.

### Example: (defun discard-eg() (exchange-point-and-mark) (point)) generates:

PC Byte Instruction
0 192 constant[0] exchange-point-and-mark
1 32 call[0]
2 136 discard
3 96 point
4 135 return

Constants Vector: [exchange-point-and-mark]

## discardN (180)

### discardN (180)

Discards up to 127 arguments from the stack. Note there is a special instruction when there is only one argument.

#### **Implements:**

if  $(n \& 8) S[n] \leftarrow TOS$ ; top -= n & 7; where n where n is the value of the operand.

**operand:** 7-bit number of items to discard. The top 8th bit when set indicates to keep the old TOS value after discarding.

#### **Instruction size:**

2 bytes

#### Generated via:

Function calls that do not use the returned value; the end of let forms in lexical binding with optimization to remove locally-bound variables.

#### Stack effect:

$$-n+0$$

Added in: Emacs 24.1. See Section 4.7 [Emacs 24], page 142.

**Example:** When lexical binding is in effect and optimization are in effect,

generates:

```
PC Byte
         Instruction
   192
          constant[0] 1
 1
   193
          constant[1] nil
 2
   137
          dup
 3
     2
          stack-ref[2]
    182
          discardN [131]
         131
 6
     84
          add1
 7
    135
          return
```

## dup (137)

## dup (137)

Make a copy of the top-of-stack value and push that onto the top of the evaluation stack.

### Implements:

### Generated via:

setq in dynamic bindings to set a value and then use it. In lexical binding, to use the first argument parameter.

### Instruction size:

1 byte

### Stack effect:

$$-0 + 1$$
.

**Example:** When lexical binding is in effect,

### generates:

```
PC Byte Instruction
0 137 dup ;; duplicates top of stack, argument n
1 135 return
```

## stack-set (178)

### stack-set (178)

Sets a value on the evaluation stack to TOS.

#### **Implements:**

 $S[i] \leftarrow TOS$ ; top-- where i is the value of the instruction operand.

Note that stack-set[0] has the same effect as discard, but does a little more work to do this. stack-set[1] has the same effect as discardN 1 with the top bit of discardN set to preserve TOS.

#### Generated via:

let, let\* and lambda arguments.

**Operand:** A 8-bit integer stack index

#### Instruction size:

2 bytes

#### Stack effect:

$$-1 + 0$$
.

Added in: Emacs 24.1. See Section 4.7 [Emacs 24], page 142.

**Example:** When lexical binding is in effect and optimization

defun stack-set-eg()
(let ((a 5) a)))

#### generates:

```
PC Byte
          Instruction
   192
          constant[0] 5
0
 1
   193
          constant[1] nil
   193
          constant[1] nil
3
          stack-set [2]
   178
          2
5
   136
          discard
 6
   135
          return
```

Constants Vector: [5 nil]

## stack-set2 (179)

### stack-set2 (179)

### Implements:

S[i] <- TOS; top-- where i is the value of the instruction operand.

Note that stack-set2[0] has the same effect as discard, but does a little more work to do this. stack-set2[1] has the same effect as discardN 1 with the top bit of discardN set to preserve TOS.

#### Generated via:

let, let\* and lambda arguments.

**Operand:** A 16-bit integer stack index

Instruction size:

3 bytes

Stack effect:

-1 + 0.

Added in: Emacs 24.1. See Section 4.7 [Emacs 24], page 142.

Example: ??

### 3.8 Unused Instructions

These instructions are not generated. In some cases, they were generated in a older version of Emacs. In some cases the instructions were planned on being used but never were. In some cases, the instructions are still handled if they appear (such as from older bytecode), but in other cases they are no longer accepted by the interperter

### Rgoto (170)

Relative jump version of see [goto], page 29.

Introduced but unused in Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

### Rgotoifnil (171)

Relative jump version of see [goto-if-nil], page 30.

Introduced but unused in Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

### Rgotoifnonnil (172)

Relative-jump version of see [goto-if-not-nil], page 31.

Introduced but unused in Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

### Rgotoifnilelsepop (173)

Relative-jump version of see [goto-if-nil-else-pop], page 32.

Introduced but unused in Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

## Rgotoifnonnilelsepop (174)

Relative-jump version of see [goto-if-not-nil-else-pop], page 33.

Introduced but unused in Emacs 19.34. See Section 4.2 [Emacs 19], page 138.

## save-current-buffer (97)

Replaced by save-current-buffer-1. See [save-current-buffer-1], page 99.

### mark (97)

Used in V 17; obsolete in Emacs 18.31. See Section 4.1 [Emacs 18], page 137.

### scan-buffer (107)

Obsolete in Emacs 18.31. See Section 4.1 [Emacs 18], page 137.

### read-char (114)

### set-mark (115)

Obsolete in Emacs 18.31. See Section 4.1 [Emacs 18], page 137.

### interactive-p (116)

```
save-window-excursion (139)
Call save-window-excursion.
Implements:
           TOS <- (save-window-excursion)
Generated via:
          save-window-excursion
Instruction size:
          1 byte
Stack effect:
           -0+0.
Obsolete since:
           Emacs 24.1. See Section 4.7 [Emacs 24], page 142. Now generates a se-
           quence of bytecode that includes calls to current-window-configuration and
           set-window-configuration
          (defun save-window-excursion-eg() (save-window-excursion 1390))
Example:
          generates:
condition-case (143)
Replaced by pushconditioncase. See [pushconditioncase], page 27,
Implements:
Generated via:
Instruction size:
          1 byte
Stack effect:
           -2 + 1.
Obsolete since:
           Emacs 24.4. See Section 4.7 [Emacs 24], page 142.
Example: (defun condition-case-eg() (?)) generates:
temp-output-buffer-setup (144)
Implements:
Generated via:
Instruction size:
          1 byte
Stack effect:
           -2 + 1.
```

```
Obsolete since:
```

Emacs 24.1. See Section 4.7 [Emacs 24], page 142.

Example: (defun temp-output-buffer-setup-eg() (?)) generates:

temp-output-buffer-show (145)

Implements:

?

Generated via:

?

Instruction size:

1 byte

Stack effect:

-2 + 1.

Obsolete in:

Emacs 24.1. See Section 4.7 [Emacs 24], page 142.

Example: (defun temp-output-buffer-show-eg() (?)) generates:

unbind-all (146)

Introduced in Emacs 19.34 for tail-recursion elimination by jwz, but never used. See Section 4.2 [Emacs 19], page 138.

## 4 Instruction Changes Between Emacs Releases

### 4.1 After 16 and Starting in 18.31

The following instructions were renamed:

- dot becomes mark (97). See [mark], page 134.
- dot-min becomes point-min (100). See [point-min], page 104.
- dot-max becomes point-max (101). See [point-max], page 103.

The following instructions became obsolete:

- mark (97). See [mark], page 134.
- scan-buffer (107). See [scan-buffer], page 134.
- set-mark (115). See [set-mark], page 134.

### Version 18 Release History

- Emacs 18.31 was released Nov 23, 1986
- Emacs 18.32 was released Dec 6, 1986
- Emacs 18.33 was released Dec 12, 1986
- Emacs 18.35 was released Jan 5, 1987
- Emacs 18.36 was released Jan 21, 1987
- Emacs 18.37 was released Feb 11, 1987
- Emacs 18.38 was released Mar 3, 1987
- Emacs 18.39 was released May 14, 1987
- Emacs 18.40 was released Mar 18, 1987
- Emacs 18.41 was released Mar 22, 1987
- Emacs 18.44 was released Apr 15, 1987
- Emacs 18.46 was released Jun 8, 1987
- Emacs 18.47 was released Jun 15, 1987
- Emacs 18.48 was released Aug 30, 1987
- Emacs 18.49 was released Sep 17, 1987
- Emacs 18.50 was released Feb 13, 1988
- Emacs 18.51 was released May 6, 1988
- Emacs 18.52 was released Aug 31, 1988
- Emacs 18.59 was released Oct 30, 1988

### 4.2 After 18.59 and Starting 19.34

jwz and Hallvard made major changes and additions to the bytecode interpreter.

The following instructions were added:

- mult (97). See [mult], page 83.
- forward-char (117). See [forward-char], page 105.
- forward-word (118). See [forward-word], page 106.
- skip-chars-forward (119). See [skip-chars-forward], page 108.
- skip-chars-backward (120). See [skip-chars-backward], page 109.
- forward-line (121). See [forward-line], page 107.
- char-syntax (122). See [char-syntax], page 124.
- buffer-substring (123). See [buffer-substring], page 100.
- delete-region (124). See [delete-region], page 122.
- narrow-to-region (125). See [narrow-to-region], page 110.
- widen (126). See [widen], page 111.
- end-of-line (127). See [end-of-line], page 123.
- unbind-all (146). See [unbind-all], page 136.

- Rgotoifnilelsepop (173). See [Rgotoifnilelsepop], page 134.
- Rgotoifnonnilelsepop (174). See [Rgotoifnonnilelsepop], page 134.
- listN (175). See [listN], page 61.
- concatN (176). See [concatN], page 92.
- insertN (177). See [insertN], page 113.

Instruction unbind-all was added to support tail-recursion removal. However this was never subsequently implemented; so this intruction was never generated.

Starting in this version, unless C prepocessor variable BYTE\_CODE\_SAFE (off by default) is defined, the obsolete instructions listed in 18.59 are not implemented.

Bytecode meta-comments look like this:

```
;;; compiled by rms@psilocin.gnu.ai.mit.edu on Mon Jun 10 17:37:37 1996
```

;;; from file /home/fsf/rms/e19/lisp/bytecomp.el

;;; emacs version 19.31.2.

;;; bytecomp version FSF 2.10

;;; optimization is on.

;;; this file uses opcodes which do not exist in Emacs 18.

### Version 19 Release History

- Emacs 19.7 was released May 22 1993
- Emacs 19.8 was released May 25 1993
- Emacs 19.9 was released May 27 1993
- Emacs 19.10 was released May 30 1993
- Emacs 19.11 was released Jun 1, 1993
- Emacs 19.12 was released Jun 1, 1993
- Emacs 19.13 was released Jun 8, 1993
- Emacs 19.14 was released Jun 17, 1993
- Emacs 19.15 was released Jun 19, 1993
- Emacs 19.16 was released Jul 6, 1993
- Emacs 19.17 was released Jul 7, 1993
- Emacs 19.18 was released Aug 8, 1993
- Emacs 19.19 was released Aug 14, 1993
- Emacs 19.20 was released Nov 11, 1993
- Emacs 19.21 was released Nov 16, 1993
- Emacs 19.22 was released Nov 27, 1993
- Emacs 19.23 was released May 17, 1994
- Emacs 19.24 was released May 23, 1994
- Emacs 19.25 was released May 30, 1994

- Emacs 19.26 was released Sep 7, 1994
- Emacs 19.27 was released Sep 11, 1994
- Emacs 19.29 was released Jun 19, 1995
- Emacs 19.30 was released Nov 24, 1995
- Emacs 19.31 was released May 25, 1996
- Emacs 19.31 was released May 25, 1996
- Emacs 19.32 was released Aug 7, 1996
- Emacs 19.33 was released Sept 11, 1996

The Emacs Lisp tarball for 19.2 is Aug, 1992. (The tarball date for 19.2 is much later; and even after the date on the 20.1 tarball.)

### 4.3 After 19.34 and Starting in 20.1

The following instruction was added:

• save-current-buffer-1 (114) as an alias for save-current-buffer. See [save-current-buffer-1], page 99.

Bytecode interpretation of read-char, which became obsolete in v19 was dropped. Bytecode meta-comments look like this:

```
;;; Compiled by rms@psilocin.gnu.ai.mit.edu on Sun Aug 31 13:07:37 1997
```

;;; from file /home/fsf/rms/e19/lisp/emacs-lisp/bytecomp.el

;;; in Emacs version 20.0.97.1

;;; with bytecomp version 2.33

;;; with all optimizations.

;;; This file uses opcodes which do not exist in Emacs 18.

#### Version 20 Release History

- Emacs 20.1 was released Sep 15, 1997
- Emacs 20.2 was released Sep 19, 1997
- Emacs 20.3 was released Aug 19, 1998
- Emacs 20.4 was released Jul 14, 1999

### 4.4 After 20.1 and Starting in 21.1

There were no instruction changes. However there were major changes in the bytecode interpreter.

An instruction with opcode 0 causes an abort.

Bytecode meta-comments look like this:

```
;;; Compiled by pot@pot.cnuce.cnr.it on Tue Mar 18 15:36:26 2003
;;; from file /home/pot/gnu/emacs-pretest.new/lisp/emacs-lisp/bytecomp.el
;;; in Emacs version 21.3
;;; with bytecomp version 2.85.4.1
;;; with all optimizations.
```

#### Version 21 Release History

- Emacs 21.1 was released Oct 20, 2001
- Emacs 21.2 was released Mar 16, 2002
- Emacs 21.3 was released Mar 18, 2003
- Emacs 21.4 was released Feb 6, 2005

### 4.5 After 21.4 and Starting in 22.1

There were no instruction changes.

The bytecode meta-comment no longer includes the bytecomp version used.

Bytecode meta-comments look like this:

```
;;; Compiled by cyd@localhost on Sat Jun 2 00:54:30 2007
;;; from file /home/cyd/emacs/lisp/emacs-lisp/bytecomp.el
;;; in Emacs version 22.1
;;; with all optimizations.
;;; This file uses dynamic docstrings, first added in Emacs 19.29.
```

#### Version 22 Release History

- Emacs 22.1 was released Jun 02, 2007
- The Emacs 22.2 tarball is dated Mar 26 2008
- The Emacs 22.3 tarball is dated Sep 05 2008

## 4.6 After 22.3 and Starting in 23.1

There were no instruction changes.

Bytecode meta-comments look like this:

```
;;; Compiled by cyd@furry on Wed Jul 29 11:15:02 2009
;;; from file /home/cyd/emacs/lisp/emacs-lisp/bytecomp.el
;;; in Emacs version 23.1
;;; with all optimizations.
```

;;; This file uses dynamic docstrings, first added in Emacs 19.29.

#### Version 23 Release History

- Emacs 23.1 was released Jul 29, 2009
- Emacs 23.2 was released May 7, 2010
- Emacs 23.3 was released Mar 7, 2011
- The Emacs 23.4 tarball is dated Jan 28, 2012

### 4.7 After 23.4 and Starting in 24.1

An error is thrown for unknown bytecodes rather than aborting.

The following instructions were added:

- stack-set (178). See [stack-set], page 132.
- stack-set2, (179). See [stack-set2], page 133.
- discardN, (180). See [discardN], page 130.

The following instructions became obsolete:

• save-current-buffer (97). See [save-current-buffer], page 134.

Is replaced by save-current-buffer-1 (114)

Unless C prepocessor variable BYTE\_CODE\_SAFE (off by default) is defined, obsolete instructions below and from earlier versions are not implemented.

- temp-output-buffer-setup (144). See [temp-output-buffer-setup], page 135.
- temp-output-buffer-show (145). See [temp-output-buffer-show], page 136.
- save-window-excursion (139). See [save-window-excursion], page 135.

Instruction unbind-all, which never was generated, was marked obsolete in this version.

The bytecode meta-comment no longer who user/hostname compiled and at what time. A message indicating whether utf-8 non-ASCII characters is used is included.

The following instructions were added in 24.4:

- pophandler (48). See [pophandler], page 26.
- pushconditioncase (49). See [pushconditioncase], page 27.
- pushcatch (50). See [pushcatch], page 28.

Bytecode meta-comments look like this:

;;; from file /misc/emacs/bzr/emacs24-merge/lisp/emacs-lisp/bytecomp.el
;;; in Emacs version 24.3
;;; with all optimizations.
;;; This file uses dynamic docstrings, first added in Emacs 19.29.
;;; This file does not contain utf-8 non-ASCII characters,
;;; and so can be loaded in Emacs versions earlier than 23.

#### Version 24 Release History

- The Emacs 24.1 tarball is dated Jun 10, 2012
- The Emacs 24.2 tarball is dated Aug 27, 2012
- Emacs 24.3 was released Mar 11, 2013
- Emacs 24.4 was released Oct 20, 2014
- Emacs 24.5 was released Apr 10, 2015

### 4.8 After 24.5 and Starting in 25.1

Instruction 0 becomes an error rather than aborting emacs.

A number of changes were made to bytecode.c.

The following instructions, obsolete since version 18, can no longer be interpreted:

- scan-buffer (107)
- set-mark (115)

You will get an error if BYTE\_CODE\_SAFE is defined.

The bytecode meta-comment no longer include the source-code path.

Bytecode meta-comments look like this:

```
;;; Compiled
;;; in Emacs version 25.2
;;; with all optimizations.
;;; This file uses dynamic docstrings, first added in Emacs 19.29.
;;; This file does not contain utf-8 non-ASCII characters,
```

;;; and so can be loaded in Emacs versions earlier than 23.

### Version 25 Release History

- Emacs 25.1 was released Sep 16, 2016
- The Emacs 25.2 tarball is dated Apr 21, 2017
- Emacs 25.3 was released Sep 11, 2017

## 4.9 After 25.3 and Starting in 26.1

The following instruction was added:

• switch (267)

## 4.10 After 26.1 and Starting in 27.1

No changes yet.

## 5 Opcode Table

In the table below, a \* before the intruction name indicates an obsolete instruction, or instruction that is no longer generated by the bytecode compiler. On the other hand, ! indicates not just an obsolete instruction, but one that no longer is interpreted. See Section 3.1 [Instruction-Description Format], page 15, for abbreviations used here, a description of how to interpret an opcode when it contains an index, and for a description of how to interpret the stack-effect field.

## 5.1 Opcodes (0000-0077)

Oct	Dec	Instruction	Size	Description	Stack
00	0			An error. Before 25.1 it is an immediate program abort! Logically stack-ref[0] but dup should be used instead.	
01	1	stack-ref[1]	1	See [stack-ref], page 18.	+1
02	2	stack-ref[2]	1	See [stack-ref], page 18.	+1
03	3	stack-ref[3]	1	See [stack-ref], page 18.	+1
04	4	stack-ref[4]	1	See [stack-ref], page 18.	+1
05	5	stack-ref[5]	1	See [stack-ref], page 18.	+1
06	6	stack-ref[6]	2	See [stack-ref], page 18.	+1
07	7	stack-ref[7]	3	See [stack-ref], page 18.	+1
010	8	varref[0]	1	See [varref], page 19.	+1
